

# C++ Functions

---

 [programiz.com/cpp-programming/function](https://programiz.com/cpp-programming/function)

Join our newsletter for the latest updates.

In this tutorial, we will learn about the C++ function and function expressions with the help of examples.

A function is a block of code that performs a specific task.

Suppose we need to create a program to create a circle and color it. We can create two functions to solve this problem:

- a function to draw the circle
- a function to color the circle

Dividing a complex problem into smaller chunks makes our program easy to understand and reusable.

There are two types of function:

1. **Standard Library Functions:** Predefined in C++
2. **User-defined Function:** Created by users

In this tutorial, we will focus mostly on user-defined functions.

---

## C++ User-defined Function

---

C++ allows the programmer to define their own function.

A user-defined function groups code to perform a specific task and that group of code is given a name (identifier).

When the function is invoked from any part of the program, it all executes the codes defined in the body of the function.

---

## C++ Function Declaration

---

The syntax to declare a function is:

```
returnType functionName (parameter1, parameter2,...) {  
    // function body  
}
```

Here's an example of a function declaration.

```
// function declaration
void greet() {
    cout << "Hello World";
}
```

Here,

- the name of the function is `greet()`
- the return type of the function is `void`
- the empty parentheses mean it doesn't have any parameters
- the function body is written inside `{ }`

**Note:** We will learn about `returnType` and `parameters` later in this tutorial.

---

## Calling a Function

---

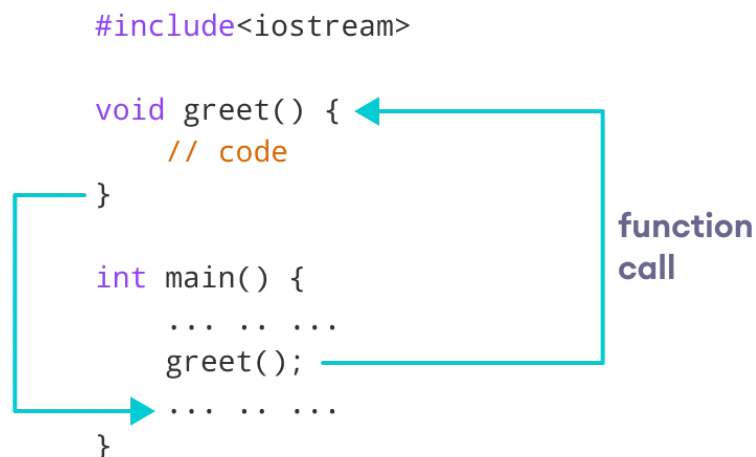

In the above program, we have declared a function named `greet()`. To use the `greet()` function, we need to call it.

Here's how we can call the above `greet()` function.

```
int main() {

    // calling a function
    greet();

}
```

How Function works in C++

---

## Example 1: Display a Text

---

```
#include <iostream>
using namespace std;

// declaring a function
void greet() {
    cout << "Hello there!";
}

int main() {

    // calling the function
    greet();

    return 0;
}
```

## Output

Hello there!

---

## Function Parameters

---

As mentioned above, a function can be declared with parameters (arguments). A parameter is a value that is passed when declaring a function.

For example, let us consider the function below:

```
void printNum(int num) {
    cout << num;
}
```

Here, the `int` variable *num* is the function parameter.

We pass a value to the function parameter while calling the function.

```
int main() {
    int n = 7;

    // calling the function
    // n is passed to the function as argument
    printNum(n);

    return 0;
}
```

---

## Example 2: Function with Parameters

---

```
// program to print a text

#include <iostream>
using namespace std;

// display a number
void displayNum(int n1, float n2) {
    cout << "The int number is " << n1;
    cout << "The double number is " << n2;
}

int main() {

    int num1 = 5;
    double num2 = 5.5;

    // calling the function
    displayNum(num1, num2);

    return 0;
}
```

## Output

```
The int number is 5
The double number is 5.5
```

In the above program, we have used a function that has one `int` parameter and one `double` parameter.

We then pass *num1* and *num2* as arguments. These values are stored by the function parameters *n1* and *n2* respectively.

C++ function with parameters

**Note:** The type of the arguments passed while calling the function must match with the corresponding parameters defined in the function declaration.

---

## Return Statement

---

In the above programs, we have used void in the function declaration. For example,

```
void displayNumber() {  
    // code  
}
```

This means the function is not returning any value.

It's also possible to return a value from a function. For this, we need to specify the `returnType` of the function during function declaration.

Then, the `return` statement can be used to return a value from a function.

For example,

```
int add (int a, int b) {  
    return (a + b);  
}
```

Here, we have the data type `int` instead of `void`. This means that the function returns an `int` value.

The code `return (a + b);` returns the sum of the two parameters as the function value.

The `return` statement denotes that the function has ended. Any code after `return` inside the function is not executed.

---

### Example 3: Add Two Numbers

---

```
// program to add two numbers using a function  
  
#include <iostream>  
  
using namespace std;  
  
// declaring a function  
int add(int a, int b) {  
    return (a + b);  
}  
  
int main() {  
  
    int sum;  
  
    // calling the function and storing  
    // the returned value in sum  
    sum = add(100, 78);  
  
    cout << "100 + 78 = " << sum << endl;  
  
    return 0;  
}
```

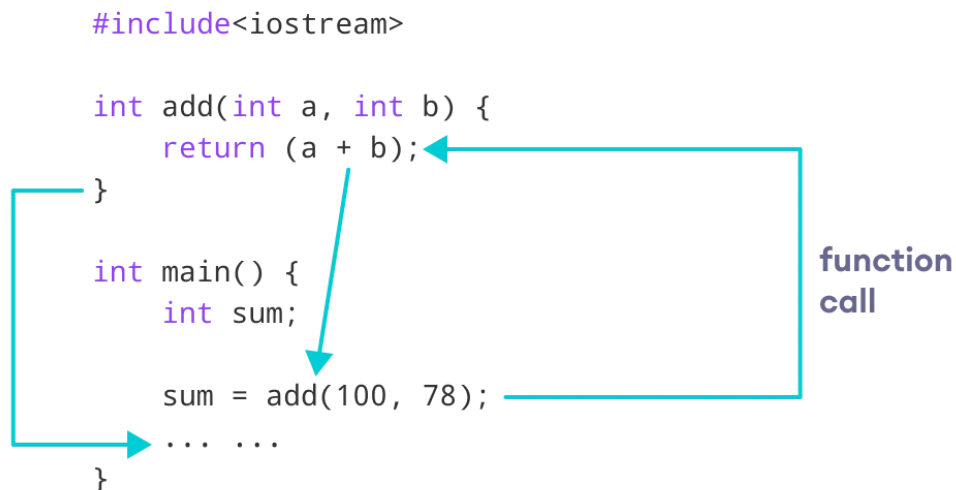

## Output

100 + 78 = 178

In the above program, the `add()` function is used to find the sum of two numbers.

We pass two `int` literals `100` and `78` while calling the function.

We store the returned value of the function in the variable `sum`, and then we print it.

Working of C++ Function with return statement

Notice that `sum` is a variable of `int` type. This is because the return value of `add()` is of `int` type.

---

## Function Prototype

In C++, the code of function declaration should be before the function call. However, if we want to define a function after the function call, we need to use the function prototype.

For example,

```
// function prototype
void add(int, int);

int main() {
    // calling the function before declaration.
    add(5, 3);
    return 0;
}

// function definition
void add(int a, int b) {
    cout << (a + b);
}
```

In the above code, the function prototype is:

```
void add(int, int);
```

This provides the compiler with information about the function name and its parameters. That's why we can use the code to call a function before the function has been defined.

The syntax of a function prototype is:

```
returnType functionName(dataType1, dataType2, ...);
```

---

## Example 4: C++ Function Prototype

---

```
// using function definition after main() function
// function prototype is declared before main()

#include <iostream>

using namespace std;

// function prototype
int add(int, int);

int main() {
    int sum;

    // calling the function and storing
    // the returned value in sum
    sum = add(100, 78);

    cout << "100 + 78 = " << sum << endl;

    return 0;
}

// function definition
int add(int a, int b) {
    return (a + b);
}
```

### Output

```
100 + 78 = 178
```

The above program is nearly identical to **Example 3**. The only difference is that here, the function is defined **after** the function call.

That's why we have used a function prototype in this example.

---

## Benefits of Using User-Defined Functions

---

- Functions make the code reusable. We can declare them once and use them multiple times.
- Functions make the program easier as each small task is divided into a function.
- Functions increase readability.

---

## C++ Library Functions

---

Library functions are the built-in functions in C++ programming.

Programmers can use library functions by invoking the functions directly; they don't need to write the functions themselves.

Some common library functions in C++ are `sqrt()` , `abs()` , `isdigit()` , etc.

In order to use library functions, we usually need to include the header file in which these library functions are defined.

For instance, in order to use mathematical functions such as `sqrt()` and `abs()` , we need to include the header file `cmath` .

---

### Example 5: C++ Program to Find the Square Root of a Number

---

```
#include <iostream>
#include <cmath>
using namespace std;

int main() {
    double number, squareRoot;

    number = 25.0;

    // sqrt() is a library function to calculate the square root
    squareRoot = sqrt(number);

    cout << "Square root of " << number << " = " << squareRoot;

    return 0;
}
```

### Output

Square root of 25 = 5

In this program, the `sqrt()` library function is used to calculate the square root of a number.

The function declaration of `sqrt()` is defined in the `cmath` header file. That's why we need to use the code `#include <cmath>` to use the `sqrt()` function.
